## Introduction

### Peripheral artery disease (PAD)

Clinical treatment with Nitinol stent

### Open problem

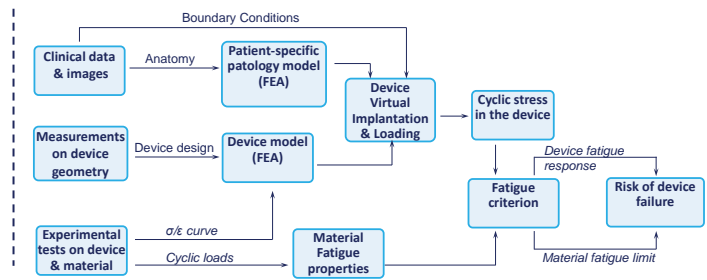

Cyclic Multiaxial loads

Nitinol stent success is undermined by long-term fatigue failure  
Stent fracture may lead to in-stent restenosis

### Predict in-vivo device fatigue behaviour

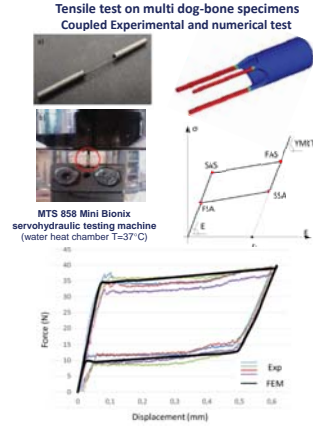

## Stent Finite Element Model: What Do We Need?

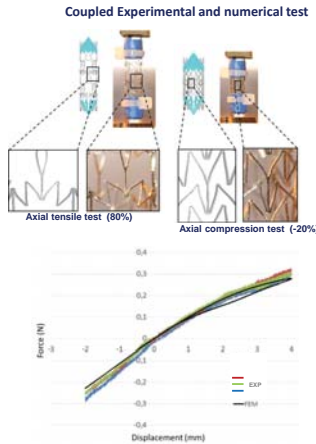

### 3D accurate geometry reproduction

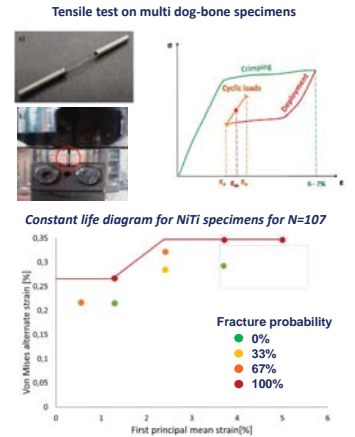

### Mechanical parameters evaluation

### Validation of the model static behaviour

### Fatigue characterization

## In-Vitro Fatigue Predictivity Validation: FE Analysis vs. Experimental Cyclic Test

Peripheral nitinol stents are subjected to cyclic multiaxial loading

Fatigue analysis highlights high risk of stent failure

Experimental test on the stent under the same loads confirm the model predictivity in occurrence and location of the fracture

A model device-specific is mandatory to obtain reliable fatigue predictivity

## Model Application: A patient specific case study

### Clinical data & images

Total occlusion of the superficial femoral artery clinically treated with a stent Lifestent

### Specific stent model

Mechanical behaviour

### Specific boundary conditions

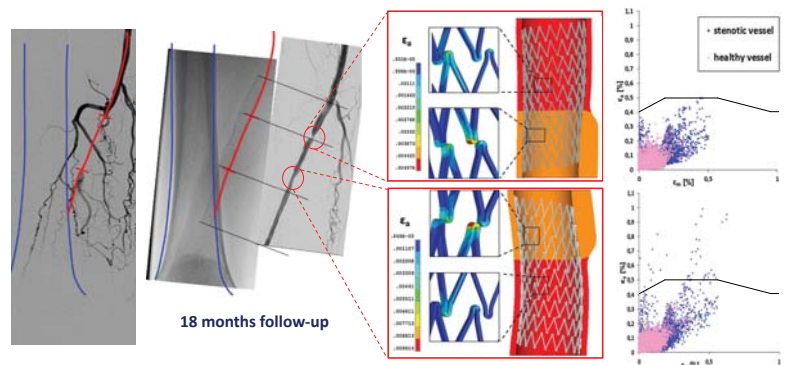

Plaque type and shape

Loading conditions

### Comparative analysis between the stent FE model and the clinical follow-up

The model predicts an high risk of failure for the specific case according to the follow-up that evidences 2 stent fractures
